What is Ethereum Virtual Machine?

Ethereum Virtual Machine

- It provides a runtime environment for decentralized applications on Ethereum platform like smart contracts.

- Instead of building an entirely original Blockchain for each new application, EVM enables the development of potentially thousands of different applications all on one platform.

- Since the Ethereum Virtual Machine is completely isolated from the rest of the main network, it is a perfect testing environment.

- Every Ethereum node in the network runs an EVM implementation and executes the same instructions.

- It has been implemented in Python, Ruby, C++, and a few other programming languages.

THANK YOU!
